

ITRI613 Databases I

Chapter 4 – Relational Algebra (Part A)

Learning outcomes

After engaging with the materials and activities in this study unit you should be able to:

- Use Linear algebra for constructing Queries and manipulate of a DBMS;
- Use the relational model which can rigorously define query languages that are simple and powerful.

Relational Query Languages

- Query languages: Allow manipulation and retrieval of data from a database.
- Relational model supports simple, powerful QLs:
 - Strong formal foundation based on logic.
 - Allows for much optimization.
- Query Languages != programming languages!
 - QLs not expected to be "Turing complete".
 - QLs not intended to be used for complex calculations.
 - QLs support easy, efficient access to large data sets.

Formal Relational Query Languages

- ❖ Two mathematical Query Languages form the basis for "real" languages (e.g. SQL), and for implementation:
 - Relational Algebra: More operational(procedural), very useful for representing execution plans.
 - <u>Relational Calculus</u>: Lets users describe what they want, rather than how to compute it. (Non-operational, <u>declarative</u>.)

Preliminaries

- * A query is applied to *relation instances*, and the result of a query is also a relation instance.
 - *Schemas* of input relations for a query are fixed (but query will run regardless of instance!)
 - The schema for the *result* of a given query is also fixed! Determined by definition of query language constructs.
- * Positional vs. named-field notation:
 - Positional notation easier for formal definitions, named-field notation more readable.
 - Both used in SQL

Example Instances

R1

sid	<u>bid</u>	<u>day</u>
22	101	10/10/96
58	103	11/12/96

- "Sailors" and "Reserves" relations for our examples."bid" = boats. "sid": sailors
- We'll use positional or named field notation, assume that names of fields in query results are `inherited' from names of fields in query input relations.

 S_1

sid	sname	rating	age
22	dustin	7	45.0
31	lubber	8	55.5
58	rusty	10	35.0

*S*2

sid	sname	rating	age
28	yuppy	9	35.0
31	lubber	8	55.5
44	guppy	5	35.0
58	rusty	10	35.0

Relational Algebra

- Basic operations:
 - Selection (σ) Selects a subset of rows from relation.
 - *Projection* (π) Deletes unwanted columns from relation.
 - $\underline{Cross-product}$ (\times) Allows us to combine two relations.
 - *Set-difference* (—) Tuples in reln. 1, but not in reln. 2.
 - Union (\cup) Tuples in reln. 1 and in reln. 2.
- * Additional operations:
 - Intersection, <u>join</u>, division, renaming: Not essential, but (very!) useful. (Part B)
- Since each operation returns a relation, operations can be composed! (Algebra is "closed".)

Projection

- Deletes attributes that are not in projection list.
- * *Schema* of result contains exactly the fields in the projection list, with the same names that they had in the (only) input relation.
- Projection operator has to eliminate *duplicates*! (Why??, what are the consequences?)
- Note: real systems typically don't do duplicate elimination unless the user explicitly asks for it. (Why not?) CSCD343- Introduction to databases- A. Va

sname	rating
yuppy	9
lubber	8
guppy	5
rusty	10

π sname, rating (S2)

age 35.0 55.5

Selection

- Selects rows that satisfy selection condition.
- Schema of result identical to schema of (only) input relation.
- * Result relation can be the *input* for another relational algebra operation! (Operator composition.)

sid	sname	rating	age
28	yuppy	9	35.0
58	rusty	10	35.0

$$\sigma_{rating>8}(S2)$$

sname	rating
yuppy	9
rusty	10

$$\pi_{sname,rating}(\sigma_{rating} > 8^{(S2)})$$

Union, Intersection, Set-Difference

- * All of these operations take two input relations, which must be *union-compatible*:
 - Same number of fields.
 - Corresponding' fields have the same type.
- What is the *schema* of result?

sid	sname	rating	age
22	dustin	7	45.0

$$S1-S2$$

sid	sname	rating	age
22	dustin	7	45.0
31	lubber	8	55.5
58	rusty	10	35.0
44	guppy	5	35.0
28	yuppy	9	35.0

$$S1 \cup S2$$

sid	sname	rating	age
31	lubber	8	55.5
58	rusty	10	35.0

$$S1 \cap S2$$

Cross-Product

- ❖ Each row of S1 is paired with each row of R1.
- * Result schema has one field per field of S1 and R1, with field names `inherited' if possible.
 - *Conflict*: Both S1 and R1 have a field called *sid*.

(sid)	sname	rating	age	(sid)	bid	day
22	dustin	7	45.0	22	101	10/10/96
22	dustin	7	45.0	58	103	11/12/96
31	lubber	8	55.5	22	101	10/10/96
31	lubber	8	55.5	58	103	11/12/96
58	rusty	10	35.0	22	101	10/10/96
58	rusty	10	35.0	58	103	11/12/96

• Renaming operator: $\rho(C(1 \rightarrow sid1, 5 \rightarrow sid2), S1 \times R1)$

Summary

- The relational model has rigorously defined query languages that are simple and powerful.
- * Relational algebra is more operational; useful as internal representation for query evaluation plans.
- ❖ Several ways of expressing a given query; a query optimizer should choose the most efficient version.
